

PLOTXY - A scientific plotting and post-processing program

A step-by-step tutorial

July 2020

New section: Postprocessing/Advanced function plots

New section: Postprocessing/Changing time unit

New feature: DFT charts now allow non-uniformly spaced samples; Fourier info button shows also RMS and PWHC

About this tutorial

This tutorial shows the basic operations to obtain the first plots from PlotXY. It shows also nearly everything you will need to make also more complex operations with the program.

Please consider that the maximum efforts have been done to make the program as intuitive as possible, therefore the learning curve should be very steep. I imagine that the duration of this tutorial for you will be around 30 minutes.

The figures shown have been made using the Microsoft Windows version of the program. Under Apple Mac they are slightly different but the elements (buttons, tables, etc.) are exactly the same. Therefore any Mac reader will be as comfortable as Windows users in following this tutorial.

This tutorial is intended for sequential reading. However, in case you strongly want to, you can jump to any of its sections by clicking on the links in the Table of Contents.

What PlotXY is and what can do for you

I propose here just a few Q&A's.

What is PlotXY? It is a program to make plots and post-processing of simulated and measured data, specifically designed for scientists and engineers.

What are the PlotXY strengths as a plotting program? It is built from the ground up having in mind serious scientific usage. For instance:

- 1) it is at ease with very large data: it loads easily files of large size (tens or hundreds of MB), and plots very fast variables having many samples (several thousands or even hundreds of thousands).
- 2) It manages effectively the scientific prefixes (“k” for “kilo”, “M, for Mega”, etc). If input data contains the relevant information, it uses the correct unit of measure (“A” for ampere, “V” for volt, etc.)

How PlotXY interacts with my other favourite programs? This program is able to read data from the well-knowns ATP simulation program, as well as from asci files (both its own “ADF” format and common versions of CSV files). For instance it reads smoothly CSV files created from the Modelica simulator OpenModelica (www.openmodelica.org). It can export plots into SVG, PNG, PDF formats.

What kind of post-processing is possible? You can make any kind of algebraic operations among the variables read from input files. You can also make the time-integral of a variable. You can also compute and plot the coefficients of the Fourier polynomial of a variable.

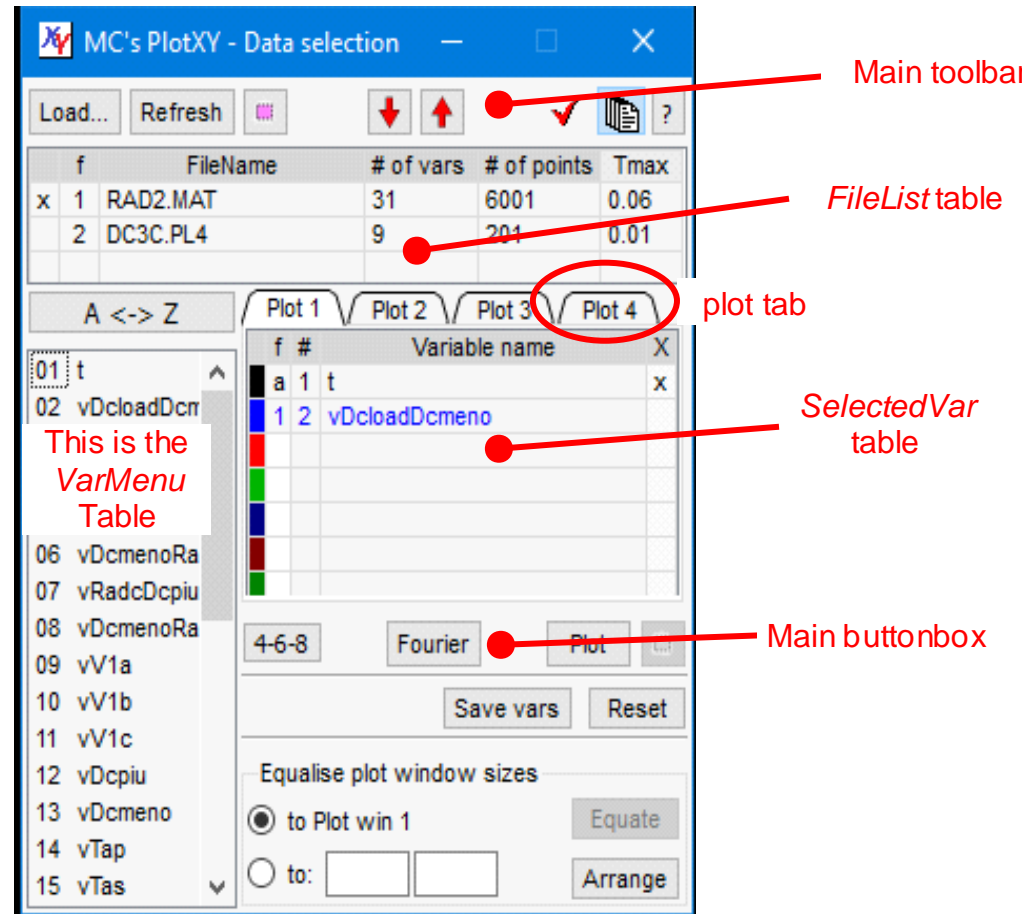

Is the program free? Yes, it is completely free. It is distributed under the open source LGPL license.

Getting to know the main windows and giving names to buttons

Before starting doing things, better is to become acquainted with the three program main windows, and to give names to their buttons.

The DataSelection Window

Once PlotXY is started, the first window to appear is the one shown below, that is the main program window.

Below you can find specific names of the toolbar tools

The FileList Table is self-explanatory. Some explanation of the SelectedVar table columns is needed instead:

- Column "f" contains the file number. In the example above we have two files; the "u" corresponding to vDcloudDcmeno indicates that this variable comes from the file number 1. The variable on the horizontal axis, here "t", must be in common with all the considered file, that's why in the "f" column, "t" row, we find the indicator "a", which stands for "all".
- Column "#" contains the variable number inside the considered file. Here vDcloudDcmeno is variable n. 2.

- Column “X”. This letter stands for “aXis”. In this column, we find a “x” on the variable to be put on the x-aXis, a “r” for variables to be plotted against the vertical y-aXis in case of twin vertical axis (see sect. Special plots: with twin vertical axes or X-Y plots”). If nothing is written on the “X” column for a variable, the default, i.e. left-y axis, applies.

The Plot window

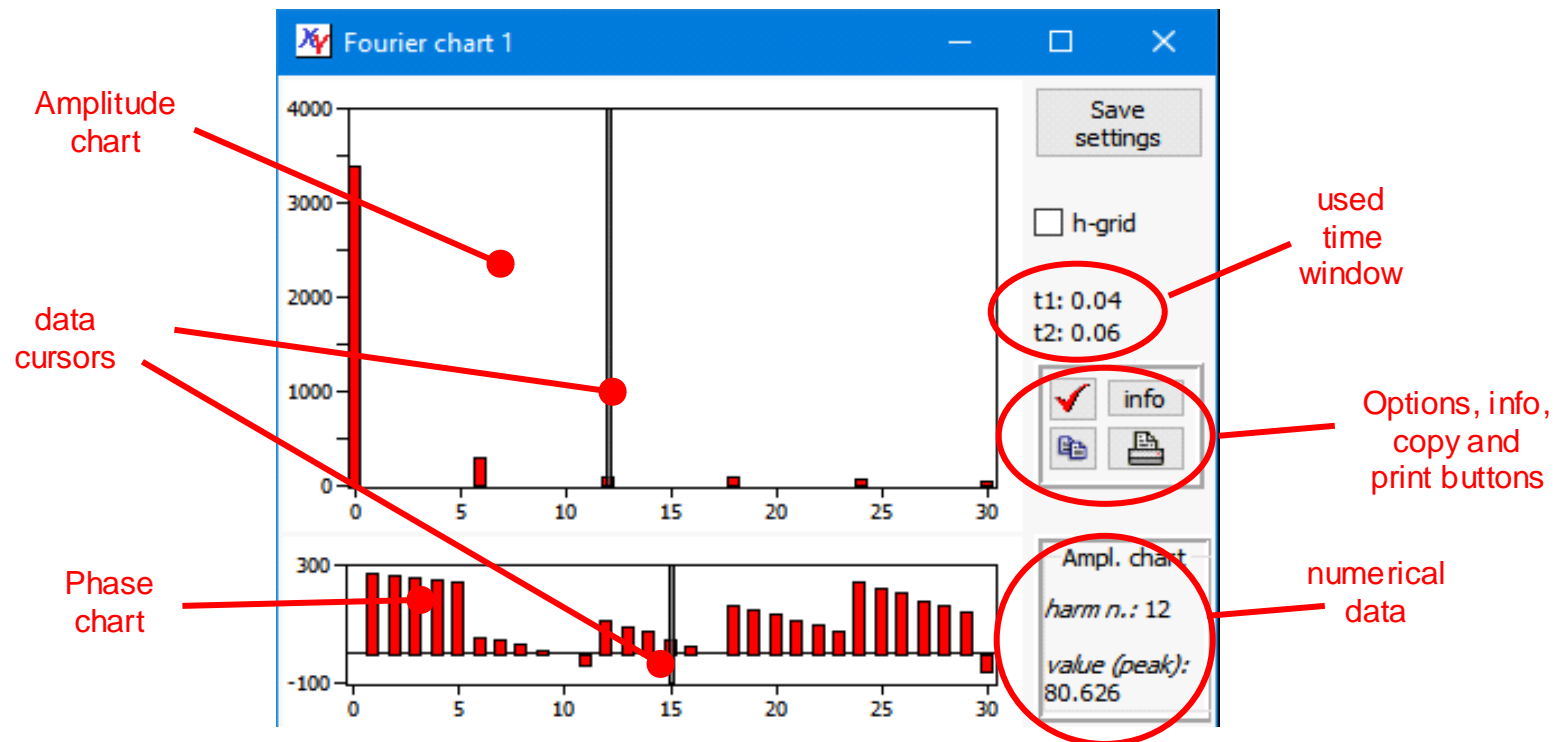

When, in the Data Selection window the plot button is clicked, the plot window is displayed.

It has the appearance shown in the picture aside (in which a simple plot from the supplied file “sample1.adf” is drawn), where names of the toolbar buttons are also given.

The Fourier chart window

The program is also able to make Fourier analysis (more precisely the i.e. Discrete Fourier Transform - DFT) of periodic signals and to display the corresponding amplitude and phase spectra. This is done using the Fourier Chart window, that is shown below along with the name of its main elements.

Doing the first things: a “real-life” experience

The first thing to do is to load one or more files. Here I show how it works using my own files, just to give ha hint about a real-life experience with the program. In [Working together using the provided files](#), instead I will propose actions that you can repeat using the sample files provided.

There are two ways of doing this:

1. Using the Load... button
2. Using the drag&drop feature of the operating system: looking at the file name in their own directory, selecting one or more of them, and dragging them onto the main program window.

Once some files have been loaded the main program window can for instance have the appearance shown below at the left side of the figure (three files) or at the right side (seven different files).

Note that the program automatically selects the first variable as the “x variable” (the one that should by default correspond to the horizontal axis). If all the loaded files share the same name on the horizontal axis, this one will be chosen.

If all the first names begin with the same first character a name containing that character and ‘*’ will be used. For instance, if all the variables begin with ‘t’ we will have a “common time” variable indicated as “t*” (see figure left above). Note that based on the first character the horizontal variable will be attributed a unit of measure, according with the following convention:

- Names beginning with 't' will be treated as being time (unit of measure is second)
- Names beginning with 'f' will be treated as being frequency (unit of measure is hertz).

If the first names in the selected files var-lists do not have all the same first character, the program gives to this common variable the name "x" and gives up trying to understand which unit of measure it might have,

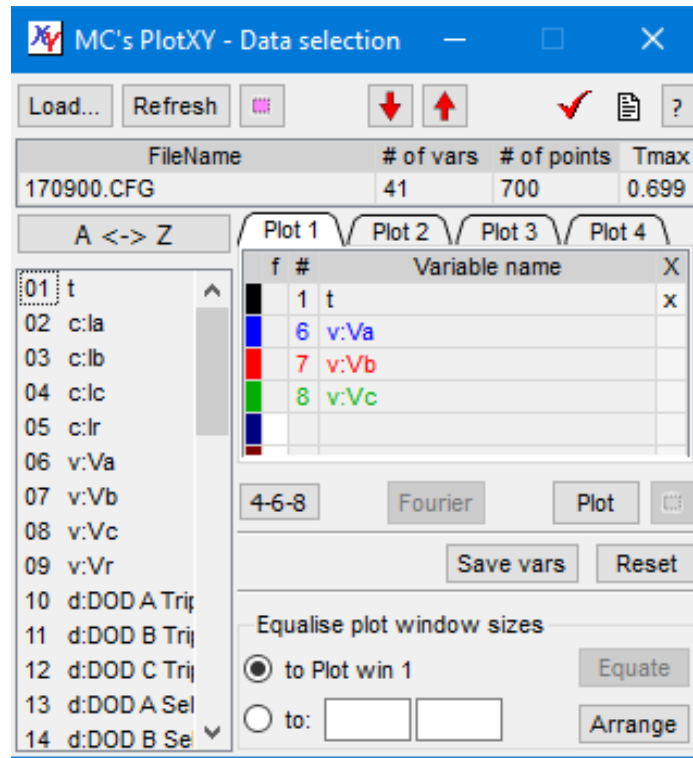

There are times, however, in which the user wants just to deal with a single file. In this case he can switch to the single-file mode, simply by clicking on the second rightmost button on the main toolbar. This way he will save valuable screen space, and have some additional features that are available only in single-file mode.

Switching into *singleFile* mode does not unload any of the already loaded files. When I clicked on the second right-most button of the toolbar from the situation shown in the right window just above here, I got the appearance shown aside (I have also reduced the window's height by acting as usual on resizable windows).

Now it is time to select and plot variables.

From the figure aside we now select (by clicking onto the respective names) variables #2, #3, #4. The window will now appear as shown below at left.

Once the variables have been selected, they can be plot simply clicking on the "Plot" button. In my example the window shown below at right appears.

As often, in this case the plot is too cluttered to see details. However, it is very simple in PlotXY to zoom: simply click and drag. To zoom out, right-click and choose whether zoom just one step or totally. Below three progressive zoom levels of the same figure are shown in three windows that, for compactness were been previously horizontally shrunk.

You might have noted a few characteristics of the plots that are produced:

- 1) Minimum and maximum numerical values on the axes are always “round” numbers. Indeed a rather sophisticated algorithm is present inside do avoid nasty numbers on the axis such as 1.2345 or 100000 or 0.000001
- 2) The unit of measure of the quantities is automatically set to kV. This is based on the variable names. If the auto-naming feature is not disabled, all variables whose name begins with “v” is taken to be a voltage. Also, time is acknowledged as such and its unit set to seconds.

The rules used for auto-setting of units of measure are as in the following table:

<i>First character of name</i>	<i>quantity</i>	<i>First character of name</i>	<i>quantity</i>
“t”	time	“a”	angle
“v”	voltage	“p”	power
“i” or “c”	current	“e”	energy

When these units of measures are used, also the standard prefixes are used as well (e.g. u for “micro”, m for “milli” k for “kilo”, M for “Mega”, G for “Giga”, etc.).

Now that you have a first idea of how the programs work and how the produced plots look like in a real-life case, let us make together some plots step-by-step using the enclosed sample files (from sample1.adf to sample3.adf).

Doing some activity using the provided files

Loading a file and doing first things

If you have gained access to this tutorial, I can assume you have already installed the program and understood how to launch the program.

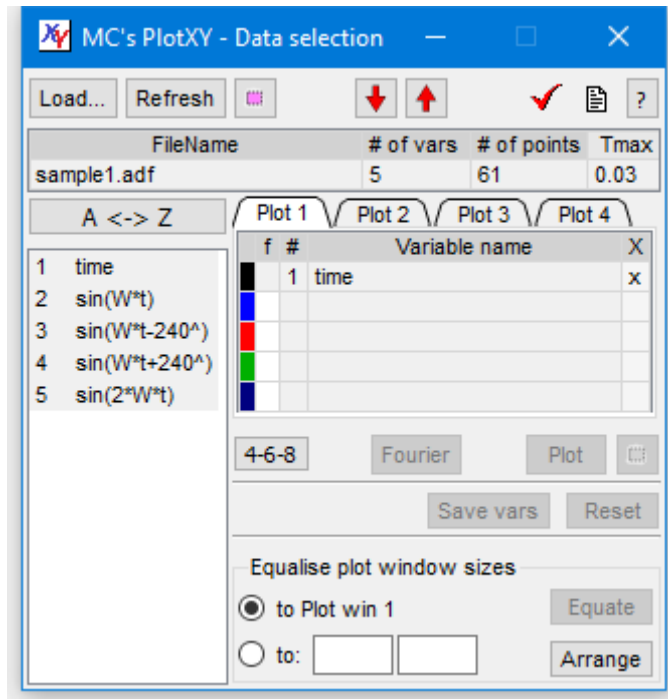

However, to launch the program the best way is to use a link you have created linking to PlotXY.exe (that you've put in a directory of your choice) and click on it.

When the file is loaded, you have two options to load a file (either using the button (Load...) or dragging a file onto the PlotXY window from the directory where it is.

Once you have loaded the program and loaded sample1.adf the program window looks like the one shown aside.

Since the file is compact and just one, we can reduce the window size to reduce its space occupation on the screen. To reduce the window size se use the usual way for resizing windows in computers using the window's borders.

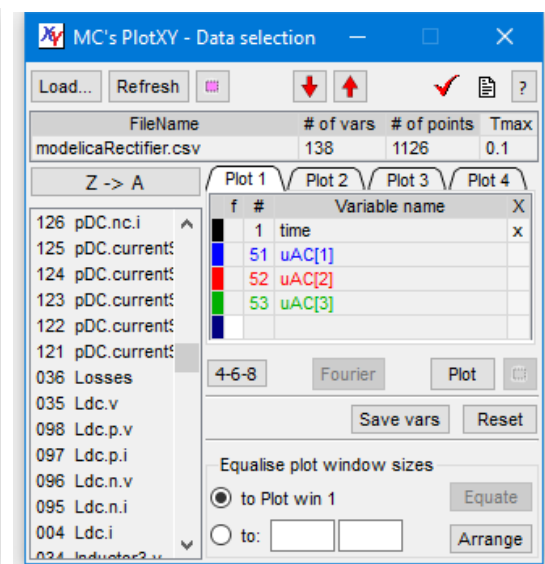

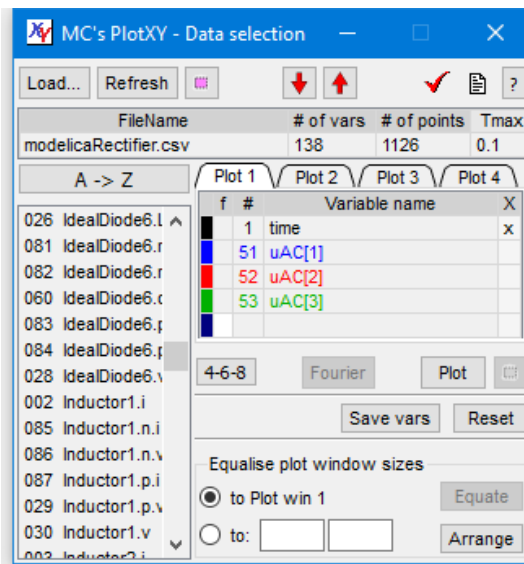

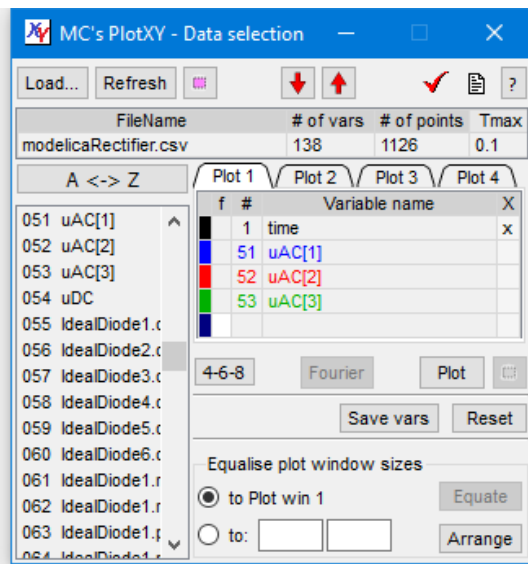

Moreover, we choose to display in the file table only one file we click on the Single/multifile button in the main toolbar

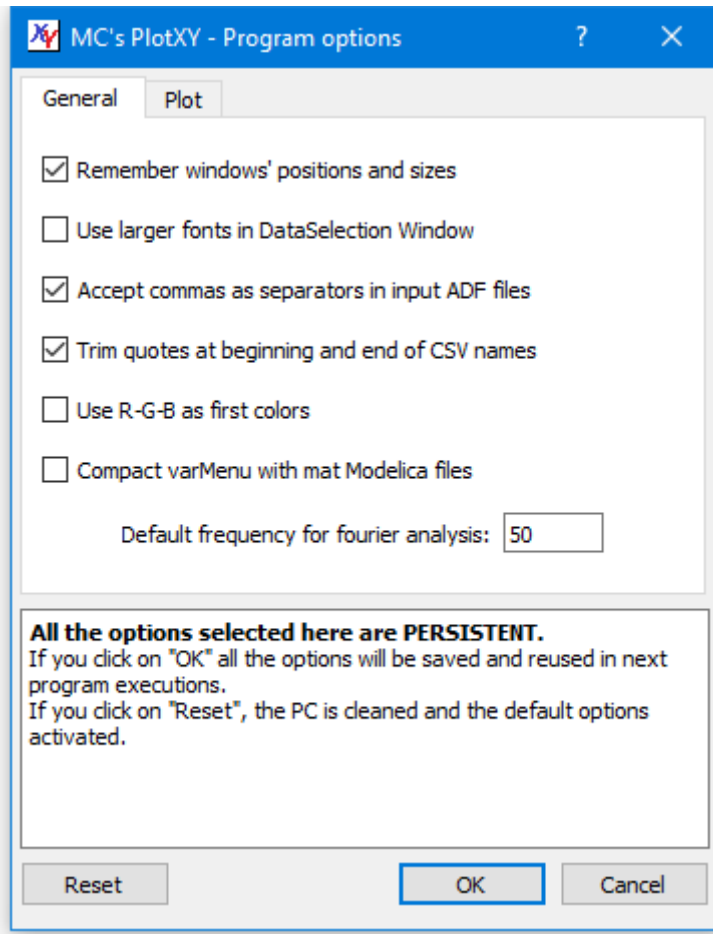

The corresponding windows will now look like as shown aside: the window is much smaller and saves much of your precious desktop area.

If you have many variables you might find it useful to sort them alphabetically in ascending or descending order using the *Var Sorting* button (three pictures below). When A<->Z is displayed the variables are listed in the same order in which they appear in their input file.

Note that sorting does not change the number attributed to each variable: for instance the selected variables remained variables N. 51, 52, 53.

Naturally, if we commonly use small numbers of files and variable and plots, we want to use small program windows ad default, without having to resize it anytime we load the program. To do this, we can set the option “remember windows’ positions and sizes”. The program options are accessed clicking on the third button from the right in the man toolbar showing a check-mark as symbol.

Several program options can be set. Here I did show just the one interests us now. Note that the program settings are written as system settings in a region of the computer storage space the operating system chooses. Under Microsoft Windows it is the Windows’ registry.

Although I don’t advise this ;-) you might want to remove the program from your hard disk and leave the computer completely clean. To do so, you have to open the program options window and click on the “Reset” button.

Making, evaluating and managing line plots

Now we want to select a variable and show its plot. To select a variable you can click on its name in the *VarMenu* table, or drag &drop it in the *SelectedVar* table. In the first case, the variable will get the first available colour, in the latter you can choose the variable colour by choosing the appropriate row.

In the figure left below a few variables from the supplied file rad2.mat re elected by clicking on their names; in the one at the right side their names are dragged and dropped, so that the wanted colours are used (the last dropped has a yellow background). The plots will have the same colours as the shown variable names..

You can also select several adjacent variables at a time: a *group* of variables. You have to keep the shift key down while clicking on the first (the uppermost) variable of the group, and then click normally on the last one.

Once one or more variable(s) is (are) selected, click on the "Plot" button to see the plot. Two examples from file sample1.pdf are below: please reproduce them as a very simple exercise.

We see that the plot contain also a legend (shown below) containing the variable names.

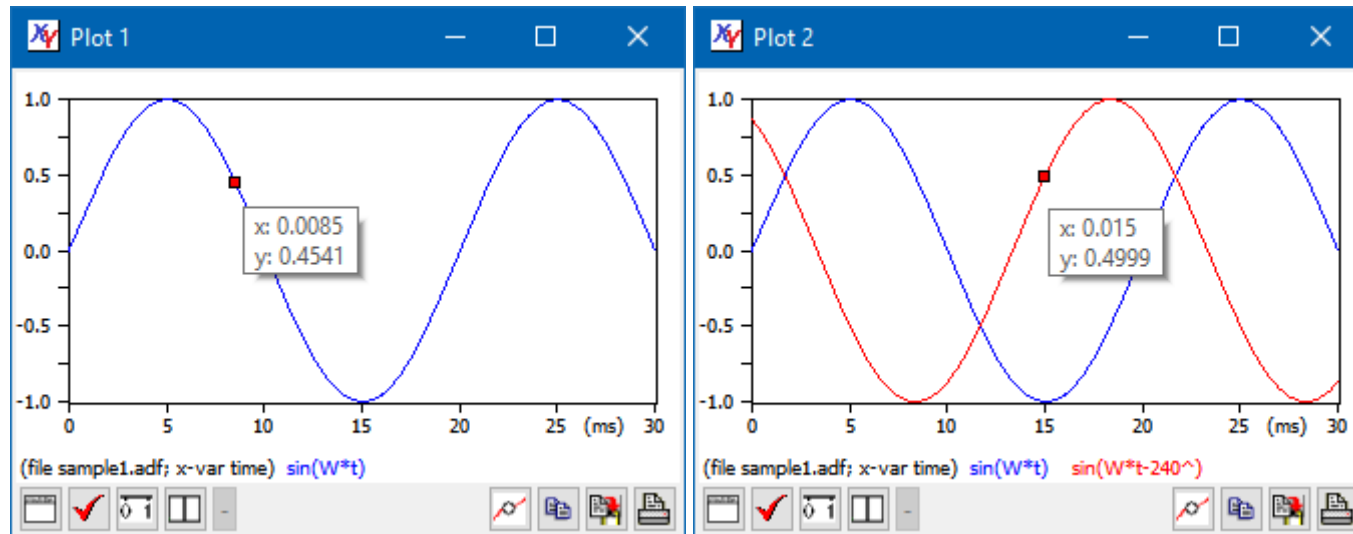

You can zoom the produced plots at will, as we've learned in the [Doing the first things: feel a real-life experience](#).

Now we perform additional actions.

Looking at data values

Consider the plots in the right picture here above. We now want to see some numerical values.

PlotXY offers two ways to do this. The first one is putting the mouse cursor near the curves. The program will find the nearest point in file and show the corresponding value on a tooltip box. Moreover, a small red rectangle indicating what point the value exactly refers to. This is particularly useful when considering plots with only a few points and therefore the actual point on file might be rather far from the mouse pointer. See the two examples below:

Another option consists of having simultaneous access to all the values corresponding to a given x-axis value. To do this, click on the *Show data* button. What happens in the cases of a single curve or multiple curves is different. Try! You will get something like what you can see down here.

In the left window the values are directly shown in the bottom toolbar (time first), while in the right one, because more space is needed, an additional small window (the **Data browse window**) is created to show the numerical values. In the first case the number of significant digits used to display the values is 4, in the second case it is 5. However, if *Exact match* is selected in the scale window (see Modifying the plot scales), in both cases the number of significant digits is risen by one, thus becoming 5 and 6, respectively.

In both cases normally the numbers shown are exactly those present in the inpt file; however, if the “interpolate” box is checked, linear interpolation is made between adjacent points, check sample1.adf file: you will see that corresponding to $t=0.0105\text{s}$ the $\sin(\omega t)$ value is -0.1563 .

In case you want to see the difference of the values one or more cuves have at different points of time, you can click on the *Show differences* button. It is located immediately at right of the *show data* button, and carries a sign “-” on it . You will get a second vertical bar such as in the two images below. Whenever you move the grey bar you get actual values; whenever you move the green one, you will get the differences (difference values are marked with an asterisk “*” at the left side of the numbers). As before, in case a single plot is shown the numbers are shown in the Plot window, otherwise in a separatate, small additional window.

Hint: you can move cursors using arrow-keys on keyboard instead of mouse. Simple left and right arrows move by one pixel left and right. If CTRL button is hold down when using arrows, movement is faster (three pixels per keypress).

For info about looking at data values when “functions of variables” are used, see sect. Function plots.

Add markers

Sometimes one needs to have a multi-curve plot clearly understandable even when printed on a B/W printer.

This can be done using the *Add markers* Button of a Plot Window.

This button has a different behaviour when the *Show data* button is up or down.

When it is up, four markers for each curve are added in automatically determined positions of the plot (see left picture below). If, on the other hand it is down, and therefore the vertical grey bar is visible, they are added in the bar position. Therefore, moving left and right that bar, the user can chose the best position for the markers. This way he can add as many markers as he wants. (See right picture below).

Adding a plot title

To add a title to the plot, simply click on the "Plot title" button in a Plot window.

Zooming and keeping zoomed

Very often, we need to have a closer look at some plot detail. To do this we want to zoom the plot. The display of a title can be toggled using the same button.

This is straightforward with PlotXY: simply we define the zooming rectangle with the mouse: we push down the left button in the top-left corner of the rectangle, drag the mouse, and leave the button once the rectangle displays what we want. While dragging the selected area is in partly transparent pink that shows what we are selecting. See the two pictures below: the left one shows zooming in action, the right one shows the zoomed plot. Try to repeat this using the supplied file rad2.mat.

We can repeat this many times, to have a look at even tiny details of our plots. See below.

In a zoomed plot we still can look at the numerical values corresponding to the plot, either focusing on the actual data from the loaded file, or on an interpolation between points (see the right picture above).

Whenever a plot is zoomed, the axes are kept clean: we have “round numbers as minimum and maximum values and on the tic-marks. Only when the zoom is very deep, PloXY gives up choosing clean axes and use whatever it can.

To zoom out, right-click on the plot area: we will have the choice between getting back one level or zoom out the plot completely.

It might also be useful, in some occasions, to add or remove plots from a plot window without updating the zoom range.

Let us do together an exercise. From rad2.mat we can plot variables 16, 17 and 18. The plot will appear as shown below at left. Then manually zoom between 20 and 40 ms. The resulting plot is shown below at centre.

We might now add or remove curves while leaving the axes range unchanged (between 20 and 40 ms horizontally, and between – 15 and 15 A).

This is done by clicking on the *Keep scale ranges while plotting* button (on the main buttonbox of the DataSelection Window) before clicking on the plot button. If that button is down, the axis scales are left unchanged. Therefore if for instance we remove variable N. 17, and then we plot keeping scales, the plot is as shown at the rightmost picture below.

Special plots: with twin vertical axes or X-Y plots

Rather often the best visualisation is when two different plots are built using the same horizontal scale but they have different vertical sizes. In these cases it may be very convenient to realize plot with two different vertical axes (here called twin vertical axes).

PlotXY allows you to create plots with several curves, while allowing you to select which one corresponds to the left vertical axis and which correspond to the right one.

This can be seen using the enclosed file sample2.mat.

The figures below show what happens if we select a voltage (variable vTas) and a current (iZtriaTap) as variables to be numerically evaluated against the left and right vertical axes respectively.

The first variable has been selected by left-clicking on its name, the second one right-clicking on its one. In the plot window we can easily understand with variables refer to the right vertical axis: their name is shown underlined.

Note: You can also right-click on the name of an already selected variable to toggle between left and right vertical axis usage for that variable.

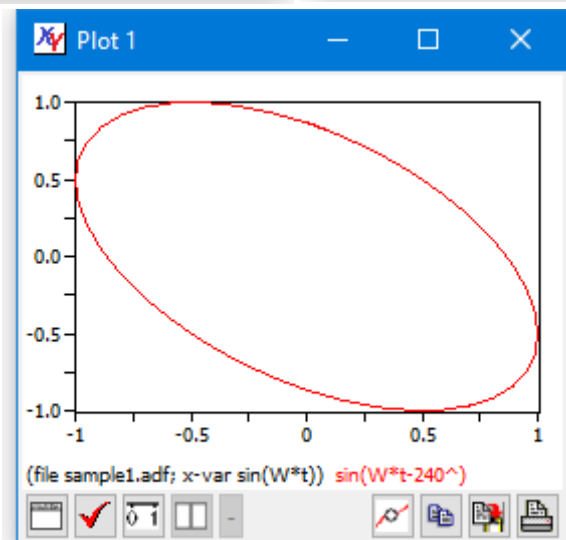

Another useful feature is the possibility to plot a variable *against* another.

This can be done only from SelectedVar tables where the selected variables come all from the same file. To make X-Y plots:

1. select the variables of interest and
2. click on the "X" column in the plot var-list of the *dataSelection* window.

When step 2 is performed, the row onto which one has clicked becomes the "x" variable for X-Y plots. When this step 2 is performed for the first time after the latest reset of the Plot var-list table the previous x-var is removed from the table, assuming that it represents time, and therefore it is not wished. In case of subsequent clicks, however, the old X variable is not automatically removed and becomes one of the y variables of the X-Y plot.

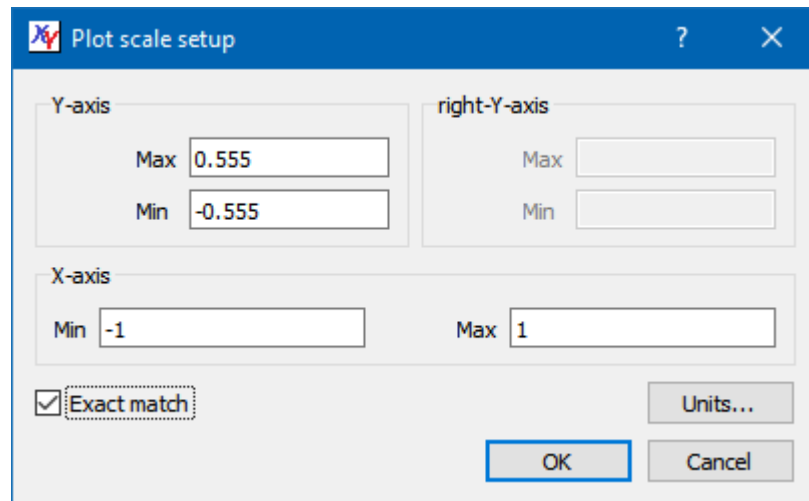

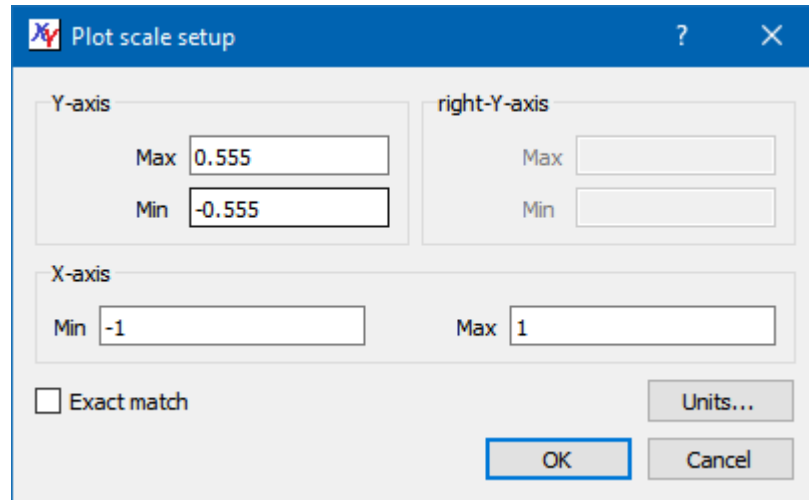

Modifying the plot scales and units of measure

We have seen that PlotXY tries to automatically find the most reasonable and readable scales on the axes. Nevertheless, the user often wants to select min and max values himself. This can be done clicking on the *Change Scale* button of the plot window. This will cause the left window below to be displayed:

If one clicks on the ok button, the scales shown in the left plot are used.

If “Exact match” is not selected the given Min and Max are still subject to adaptation by the program to ease readability, otherwise the exact scale ranges chosen by the user are used. Compare the following pictures:

When *Exact match* is selected, the number of significant digits used to display values with data cursors (see Looking at data values) is raised by one and brought to 5 or 6, depending on whether the numerical values are displayed in the *Plot window* or in the *Data browse window* (compare sect. “Looking at data values”). This is because it is intended that when the user requests *Exact match*, he wants more precision everywhere.

From some examples above, the reader might have note that the program tries to show reasonable unit of measure on the axes. For instance, variables starting with “v” are interpreted as being voltage, and the chosen unit of measure is “(V)”. This automatic determination of units of measure has important features, which are described in detail in section “Automatic Units of measure and prefixes”. Here I just want to say that the user can manually select his axis labels, clicking on the “Units...” button of the “Plot scale setup” window shown just above here.

When the user clicks on that button, the following *Units dialog* is displayed.

It allows selecting the units for any of the three axes.

When the first checkbox is selected units can be SI compliant. For example it is easy to produce units such as m, Nm, N·m, N/m, Ω, Ωm, μF, N/m², N·m⁻². To write these units, write “w” to get Ω, “u” to get μ; any digit is interpreted as being an exponent (possibly preceded by a sign), any “.” as a dot indicating product. It may happen that the user wants to use a non-SI compliant unit of measure, such as “p.u.” To do this, it is necessary not to use smart units, unchecking the first checkbox. Thus avoiding the special interpretation of dots and character “u” necessary for smart units.

If a new plot is created using the “Plot” button on the DataSelection window the units selected in the units dialog are not used for it: they might be obsolete! If, however, before clicking on “Plot” the user selects the “Keep scale ranges while plotting”, since scale ranges are kept, it is obvious that also the units of measure are expected to be correct, and existing user units are therefore used.

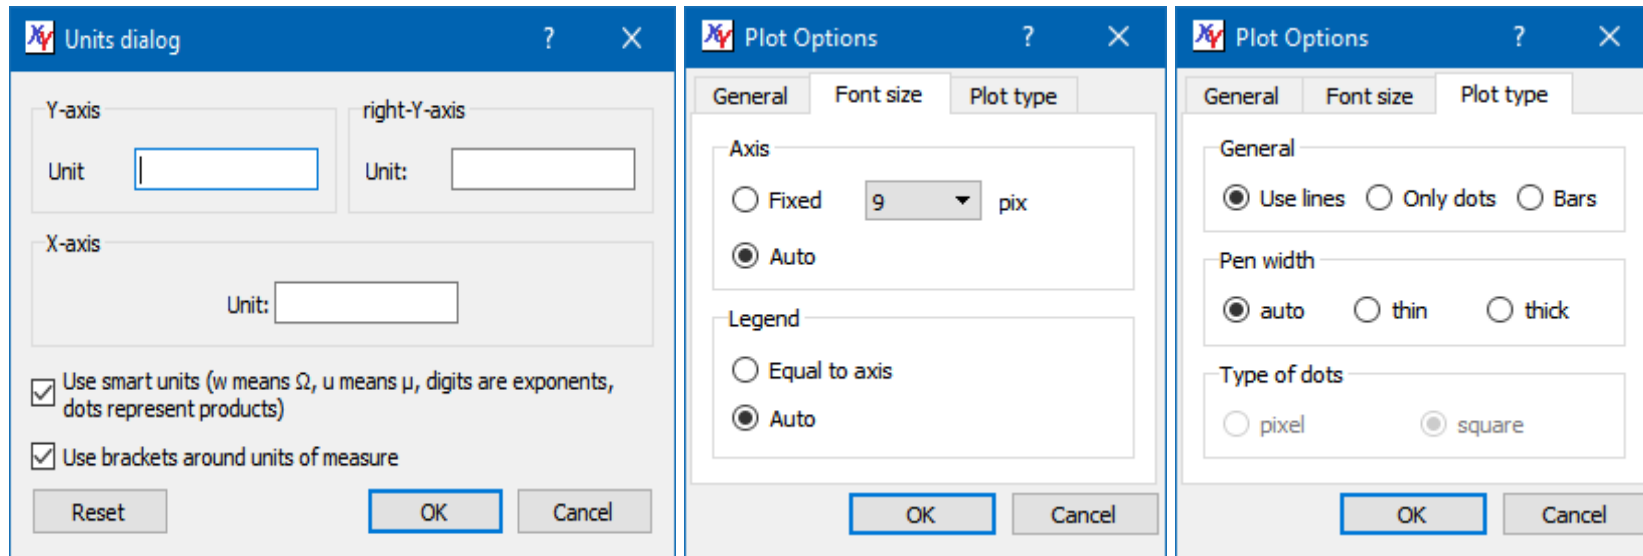

Note that the unit of resistance ohm can correctly be displayed as a Greek uppercase omega.

Changing the plot type and appearance

In the previous section, line plots with linear scale on the axes were shown.

Naturally, there exist several options to change the appearance of the plot. To explore them, try to click on the *Plot options* or *Change scale* buttons.

Click for instance the *Plot options* button. A window like the ones shown below appears. The window has three tabs displaying different options each. The meaning of the options is self-explanatory.

Two examples of the application of some plot options are shown below: General|Display Grid (left), Plot type|pen width|thick and Font size|axis|dixed 12 pts (right).

When you use a log axis, the marks on the axes and gridlines will be at 2x, 4x, 8x the main power of ten.

There are cases in which line plots are not the best way to show a plot. If we want to see only the point read from file we can use *General/only dots* option. This is done in the bottom-left plot for the first variable from sample1.adf file.

Finally there are files in which the X-Y correlation is weak; this can be shown using a cloud of points. In this case small squares to show points are too large, and it is better to use single pixels. This is done in the bottom-right plot, using variable X2 from the MorkSwarm.pl4 file

There are also cases in which instead of line plots the user needs to use a bar chart. This is done in the bottom-left plot (from sample1.df) in full scale, and in the bottom-right in a zoomed fashion. The bars whose second end falls outside the zooming window are shown greyed..

Finally scales can be linear, log, and dB. Two examples from sample2.mat are shown below

The customisation you do using the *Plot Options* button are valid for the current plot. The default graphical characteristics of the plots, e.g. those valid when plots are first created, decided at program level, using the *Program options* button of the program main window.

The Change scale button allows to manually change axes scales: this allows more flexibility than zooming: you can pan or choose detailed scaling. In the bottom-left plot the variable `vDcLoadDcmemo` is shown between 0 and 400 V, overriding the default scales.

In the bottom-right zooming on the horizontal axis is made.

Normally the user selected scales in the *Plot scale setup* dialog are subject to some refining by the scale determination inner engine to allow easy numbers on the numerical tic marks. If, however the user wants total freedom in choosing minimum and maximum values of an axis, he can attain this checking the Exact match checkbox. See the example below.

Using several program windows

Starting from the same files and variables you can show plots in different windows. Each window has its own setups, line style, scale, data-browse window, etc. A four-window example is shown below.

In case the users need more windows, he can use the “Select max number of plots” (indicated as “4-6-8”) - button, to rotate between three different maximums plot windows: 4, 6, 8. The appearance of the DataSelection window becomes as shown below

Addition comments on these windows are in sect. “Additional information/Management of the plot windows.”

It may be useful to have all the windows equal to each other or to a given size; also rearranging all plots can be helpful. To do this, PlotXY offers the tools present in “Equalise plot window sizes”. You can choose whether to equalise all windows to plot 1 size, or to a specified size.

Note that PlotXY tries to equalise also Fourier windows to the specified size: Starting from January 2020, equate button will equate also Fourier Windows. However, since they have a different structure from plot's, it might be impossible to equate a fourier Window exactly to the size of plot1, because minimum window size might be hit.

If the have a SelectedVarTable with four plot windows (the default), the plot windows are positioned as a 2x2 matrix, following the natural direction of western writing. In case of 6 or 8 plot windows, the matrices are 3x2 and 4x2 respectively.

Each fourier window, up to the sixth, is placed immediately below the corresponding plot window: this can cause some plot window to be (partially or totally) covered. Seventh and eight fourier windows are not rearranged.

After rearranging, the fourier windows are put on top of any existing plot windows; after resizing the plot windows are put on top of Fourier's. Therefore, arrange and resize buttons can also be used to put Plot and Fourier windows on top of the others, respectively, especially for equated-arranged windows.

Customising plot line colours and type

PlotXY, by default, selects solid lines for curves. The colour can be easily chosen by drawing curves in the SelectedVar table row carrying the desired colour.

However, more customisation is possible. By clicking on any of the coloured boxes in the SelectedVar Table, the Customise palette window is displayed, which has the appearance shown below:

The instructions on how to use this window are displayed. Custom colours having checkbox checked will produce dashed curves.

The text “Selected Color” will be displayed in the colour which has been selected buy clicking in any coloured cell of the Standard row.

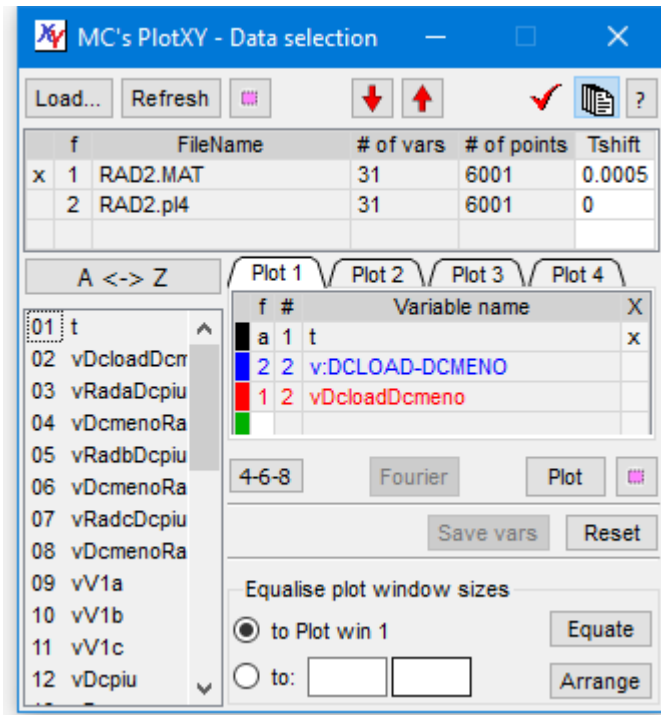

Postprocessing

PlotXY, in addition to plotting data from files, allows some post processing: finding the Fourier polynomial and making the corresponding bar charts, and creating new variables that are algebraic combination of others, or integral of others. These capabilities are discussed in this section.

Shifting time

In some cases, especially when we want to align in time measured and simulated curves, we want to add some offset to the time scale of one or more files. This can be done clicking on the cell named “Tmax” on the FTable of the DataSelection window. Once that cell is clicked, the situation changes, and “TShift” field is shown in place of Tmax. Furthermore, the corresponding cells get a white background, to indicate that they can be written.

In the example shown below two files different in name but containing the same data are used. Rad2.mat, is retarded by 0.5 milliseconds and the result is shown in the plot at the right side of the DataSelWindow below.

Another situation when shifting time might be useful, is when we want to zoom deeply at the right region of a long simulation. In case zoom is so deep that the tics numbers on the axes are all or nearly all equal (considering that the number of digits to display them is limited) understanding of horizontal axis is tricky. In this case shifting can solve the issue, as shown below: we need to have a close look at the last 10 ms of a long simulation lasting 30s. In the plot without time shifting the horizontal scale is hardly read; in the below plot, where we have shifted time so that the positive numbers are just the final 10 ms, the horizontal scale is perfectly understandable.

Changing time unit

The user can change time unit from second to hour, to day, to second.

To obtain this behaviour right-click on the time variable in the SelectedVarTable.

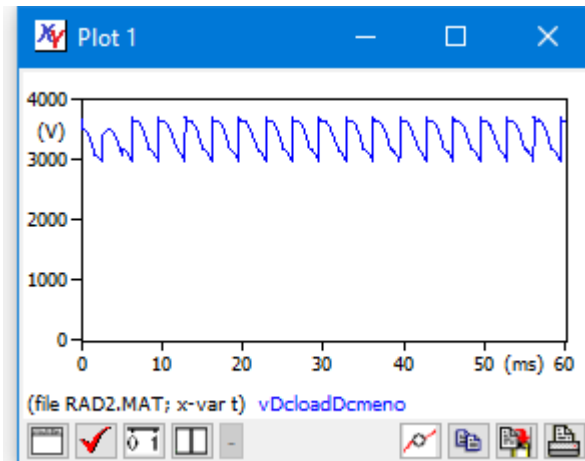

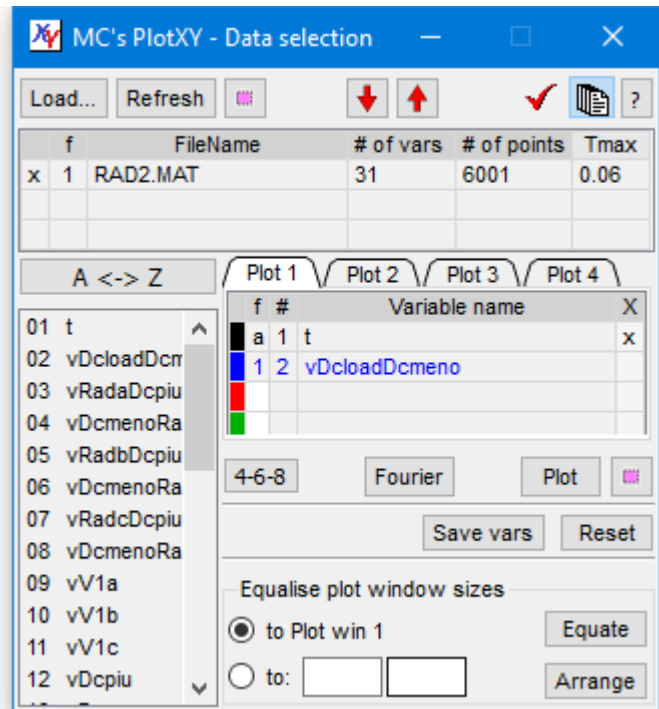

Creating and managing Fourier Charts

Electric and sound engineers use a lot Fourier decomposition of periodic waves.

This is supported by PlotXY. Starting from January 2020, a **non-uniform DFT** algorithm is used, so now it is not required anymore to have constant sampling interval to perform correct Fourier charts.

To make a Fourier chart only one variable must be selected. Then, simply click on the "Fourier" button. The program will try to choose the best parameters for general usage. In particular, it assumes that the simulation, after a possible initial transient has stabilised. Therefore, using the default frequency (that can be selected by means of the Plot Button of the DataSelection Window) it uses the last period of the available data to make computations.

Take for instance the following pictures, obtained using the supplied rad2.mat file. Here the default frequency is 50 Hz and the simulation goes from zero to 0.06 s, it will use as default the last twenty-millisecond period, for the analysis.

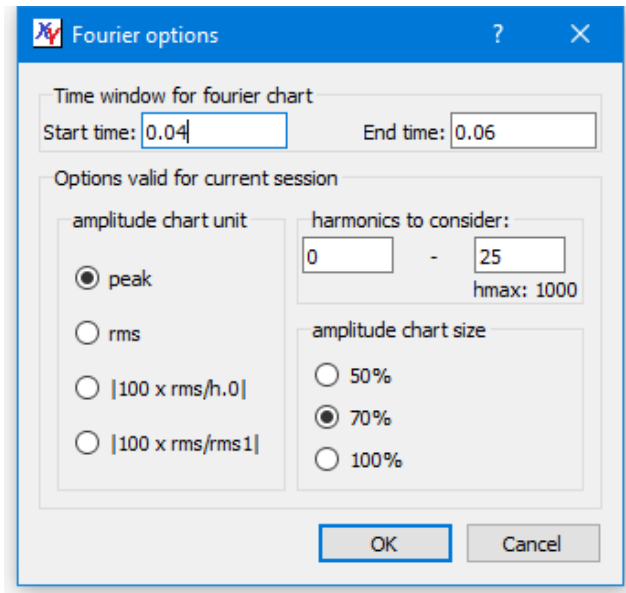

Once the chart is shown, you can move around the data cursors to see numerical values in the bottom-right part of the window.

You can zoom the chart. An example is shown below (on the left). The bars that fall into the plot are shown as usually in red (bounded by black rectangles), while the bars that are higher than the available vertical space are shown greyed.

Customising Fourier charts

The Fourier Chart can be customised in several ways clicking on the Fourier Options button. The window that appears has the aspect shown below.

Note that the numerical values can be shown in the Fourier Chart window in four different values:

- peak of sine components (DC component unchanged)
- rms of sine components (DC component unchanged)
- all harmonic components (rms values) as the percentage to the DC component value (100 x rms/h.0)
- all harmonic components (rms values) as the percentage ratio to the first harmonic rms value (100 x rms/rms1).

By default, the program considers:

- a time-range between the T_f and $T_f - 1/F$ (where T_f is the simulation final time and F is the default frequency as defined in the Program Options window).
- the harmonics between 0 and 40. The number 40 was chosen because this is the maximum order considered by IEC 61000-3 series.

These defaults can be overridden clicking on the “Fourier options” button, just left of “info” button. Note that the maximum shown (in the example above max: 1000) is a recommended maximum based on signal’s Nyquist frequency.

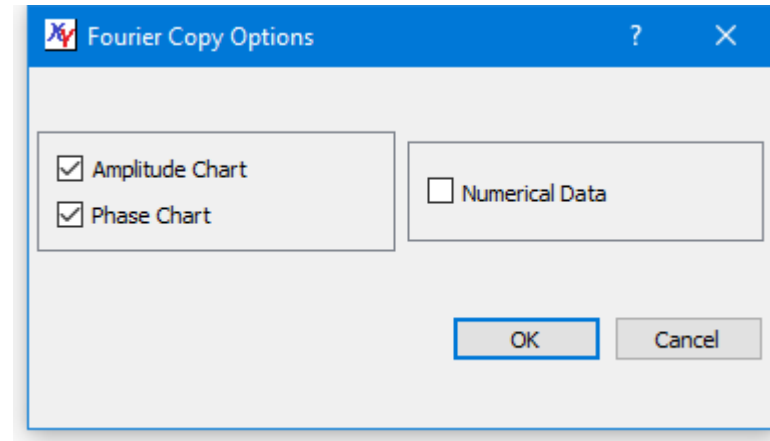

If we write a periodical variable $x(t)$ as $x(t) = A_0 + \sum_1^\infty A_k \sin(k\omega t + \alpha_k)$, by default the program and plots the values A_k and α_k k being between 0 and 40. So, it considers the peak values. By means of the “Fourier options” button these defaults can be overridden. Note that, since A_0 is the signal average in the period considered ($A_0 = \frac{1}{T} \int_t^{t+T} x(\tau) d\tau$), it can be negative.

Also note that:

- each plot window can have his own Fourier Chart, so different Fourier charts can be visually compared showing them simultaneously
- the variable for which Fourier chart is done can be a function of other variables (see *Function plots* for details).

Exporting bar charts or numerical values

To export the obtained bar charts or the numerical values the “Copy” button can be used. The dialog displayed has the following aspect:

And is self-explanatory.

Note that the number of numerical data copied equals the number of harmonics considered (defaulted to 40); moreover the numerical values of amplitudes are copied in the same units chosen using the button “Fourier options (cf. sect. About this tutorial).

Additional info

The “info” button allows seeing some miscellaneous parameters i.e.:

$$RMS = \sqrt{\sum_n^N A_{k,rms}^2} \quad THD_0 = 100 \sqrt{\sum_1^N A_k^2 / A_0} \quad THD_1 = 100 \sqrt{\sum_2^N A_k^2 / A_1}$$
 n and N being the minimum and maximum number of “harmonics to consider” chosen in the “Fourier Options” dialog. For RMS computation $A_{k,rms}$ are the RMS values of individual sine harmonics, ($k>0$) and the DC component ($k=0$).

Note that:

- if the min number of harmonic computed is above 1, THD_0 is not computed since A_1 is not available; if it is above 2 THD_1 is not computed as well
- If N is chosen equal to 40, THD_1 on a voltage gives the value defined as THD by IEC 50160
- if $N=40$ THD_1 on a current is related with THC of IEC 61000-3-12 by: $THD_1=THC/I_1$
- if $N=50$ THD_1 on a voltage gives the value defined as THD by IEEE 519
- if $N=50$ THD_1 on a current can be used to estimate Total Demand Distortion (TDD) as defined by IEEE 519

- THD_0 is an extension of the THD concept that could be used for DC systems. However, the program author is not aware of IEC standards using this quantity.

In case the harmonics analysed contain the range 14-40, also the PWHC parameter is shown computed as per IEC 61000-3-12:

$$PWHC = \sqrt{\sum_{k=14}^{40} k I_k^2}$$

Function plots

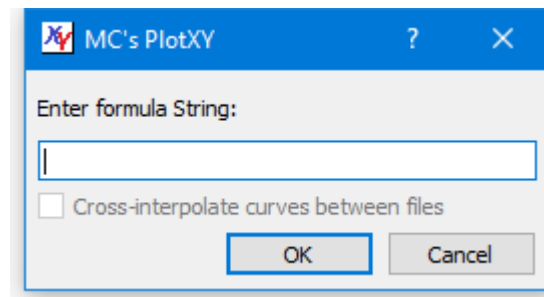

PlotXY not only allows power display of the contents of your variables, but also can manipulate your variables to obtain new ones and plot them. You can for instance sum, multiply, divide your variables. You can also take a function of your variables (see sect. “an be expor”). Parentheses are allowed. In a way, we can say that we can create a function of your variables and plot that function. Because of this, this feature has been called “Function plot”

You can also request the time integral of a variable or an expression. In this case, the string you enter to define the function must begin with “int” and end with “)”.

To define functions, you access your variables by a *compact name* built according to the following conventions:

- In general, the compact name indicates the file number and variable number with the scheme “f#v#”. For instance, variable number 3 from file number 5 has as compact name “f3v5”
- To indicate Variables from the *Selected file* (that is indicated by a “x” in the first column of the *File list* table) the file indication can be dropped. For instance the 5th variable from the Selected file can just be indicated ad “v5”.

Functions are defined by clicking on a cell in the “f” column of the *File list table* in the *Data selection* window. A small window will appear prompting you to introduce the string defining your function. It will have the following aspect:

Note that the checkbox named “cross-interpolate curves between files” in the current version will always remain unchecked. In the current version of the program, that disabled checkbox has been introduced to remind the user that no cross-interpolation will be done. This means that the program assumes that in case of function of variables involving variables from different files, the program assumes that all the samples refer to the same time instants. Necessary (but not sufficient) for this is that the numbers of points are exactly the same for all the files involved in the same function of variables.

The allowed operators between variables are the following ones: +, -, *, /. As usual, * and / take precedence over + and -. Obviously, division requires care, since there might be division by zero. If division by zero is detected a dialog box will be issued and computation of the function of variable will be stopped.

Valid strings for instance are: “v9-v10”, “2*v1-v2/5”, “V1+1e3*v2”, “1e-3*v1”, “f1v1+f2v2+f1v3”, “v1-(v2+v3)”, “10*v9+20”, “int(v2+v3)”,. The latter example requests the integral between t=0 and the generic time t of v2+v3.

The first and last strings are used in the examples are shown below. The integral is shown in the same plot along with the function to be integrated for the maximum clarity.

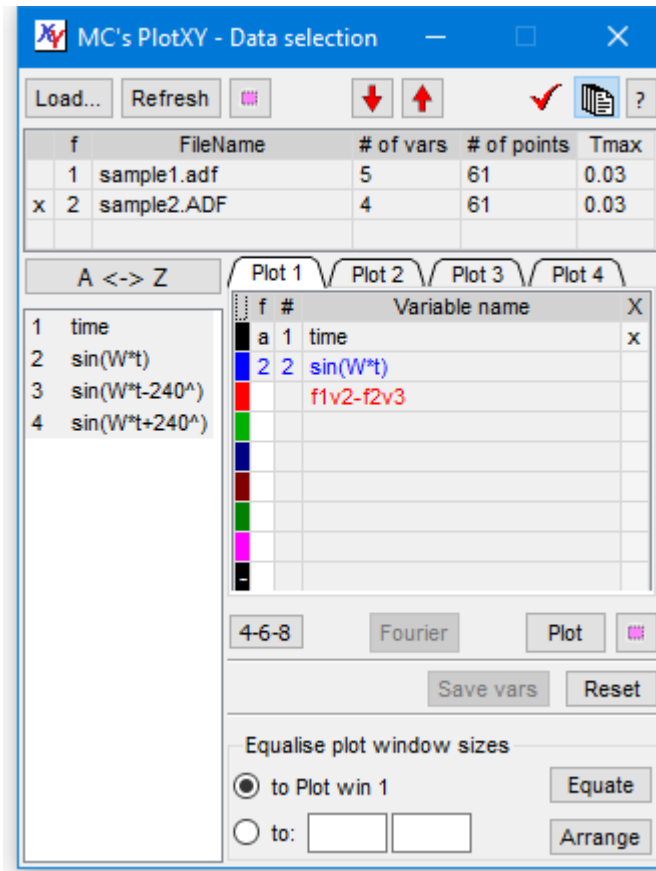

NOTE. The name of the function is just indicated as “f1”, “f2”, etc. However, to ease analysis, if the mouse is left above the variable name shown in the plot window, a full representation of the formula is shown as a tooltip.

For instance, in in the picture right below the mouse is left on “f1” in the plot window the user will see in a tooltip: “vV1a-vV1b”

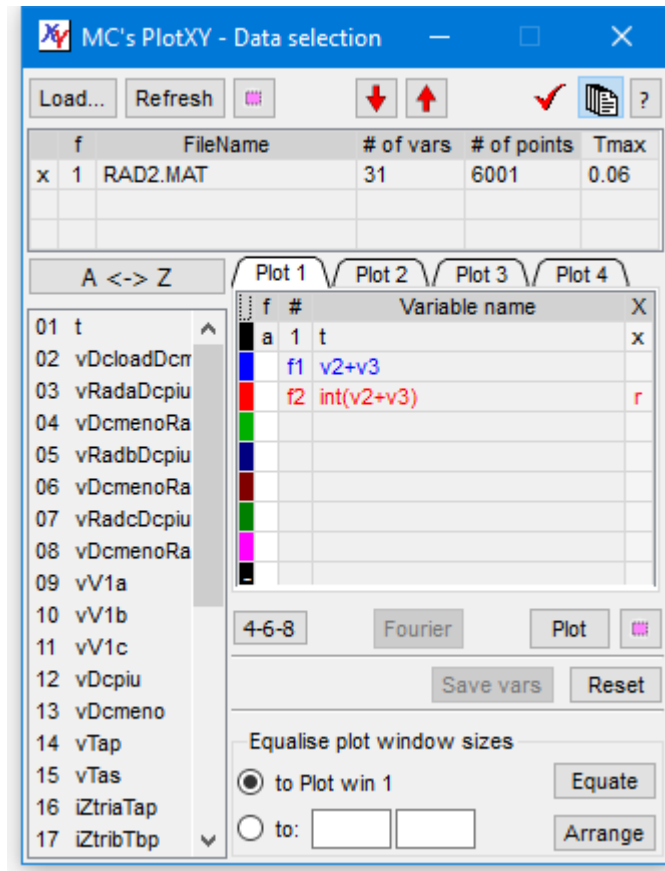

Note that If you hold the mouse pointer onto the function name in the plot window you get a full indication of what that function means (here “vV1a-vV1b”).

In case a function of variable mixes variables from different files, each file is referred to as f#: f1 for file num 1, f2 for file num 2, etc. See next figure. Remember, as already noted, that the two files must have the same time instants at which the function is to be evaluated, and the program just verifies that the numbers of points are the same for all the involved files.

Another interesting example of function plots is shown below:

NOTE: integrals are useful to calculate energy flows. For instance $\text{int}(f \cdot v)$ and $\text{int}(u \cdot i)$ will calculate the mechanical energy and electrical energy if f , v , u , i stand for force, speed, voltage, current respectively.

Finally consider that also the x variable can be a function of variable. Compare the two plots below:

Advanced function plots

In addition to algebraic manipulation of variables, in more recent PlotXY versions you can also use a function of existing variables. Available functions are: $\sin()$, $\cos()$, $\tan()$, $\sinh()$, $\cosh()$, $\tanh()$, $\exp()$, $\sqrt{}$, $\arcsin()$, $\arccos()$, $\arctan()$, $\log()$, $\text{abs}()$. If for instance you want to compare a quasi-sine wave resulting from a simulation with a pure sine wave, as mathematically determined, you can do this easily using function plots. This is shown in the figure below (we must imagine that $\sin(W*t)$ is something resulting from a simulation).

Another example of advanced use of function plots is to add horizontal rows to plots, to check values against a specific value. This is shown in the right plot in the picture below, where we want to check our plot against the value 0.6.

Working across sessions

PlotXY helps to re-enter rapidly the preferred working environment in new sessions with the possibility to save program state, to save Fourier settings, and to automatically load files. This is detailed in this section.

Customising the program behaviour allows more consistent experiences across sessions as well.

Saving Program State

When we work on PlotXY we load files, select variables, define functions, make plots.

When we close it, all this setup is in general lost. To avoid this, one can “save Program State” , i.e. the list of files loaded, variables and functions per file and plots shown, so that he can reload it again at a later time. The state is automatically stored in the Operating System’s program setting area (in Windows this is the Windows registry) and can be recalled at will.

To save the program’s state click on the “Save state” button on the main toolbar of The DataSelection Window.

Note that when working with PlotXY it may happen that a plot shows contents that does not correspond to the corresponding SelectedVar table. For instance we could select in the Plot1 SelectedVar table variables X and Y; plot them, and select a different set of variables without hitting the plot button again. When the program state is restored (clicking on the Load state on the Data Selection window), however plots always correspond to the corresponding SelectedVar table contents, as if the user has just hit the plot button.

As regards Fourier plot, PlotXY keeps trace of which plot table (e.g. “plot1”) is displayed when the fourier chart was last clicked. When reloading the state, if a single variable is present on that table, that variable’s fourier chart is drawn. This is done simulating a click on the “Fourier” button: therefore Fourier chart is done using the default settings (initial and final time, harmonics range, etc.).

NOTES:

- Fourier plots are not automatically generated when restoring the program state.
- The plot’s appearance (line vs bars vs dots, zoom state) is not stored.

Saving Fourier chart settings

While *Saving Program State* means to save which files are loaded and which variables and function plots (see section “Function plots”) are selected for each file, there are settings specific to Fourier Chart that can be saved from within the Fourier window itself.

When Fourier chart’s window “Save Settings” button is clicked the following settings are saved:

- whether the h-grid box is selected
- all the options selected in the “Fourier options”

Note that the first time in a session Fourier button is clicked, the interval in which to analyse the selected curve is automatically computed based on the default frequency in the Program options window, as follows:

$$t_1 = t_{end} - \frac{1}{f}; \quad t_2 = t_{end}$$

Where t_{end} is the final time of the current simulation, and f is the “Default frequency for Fourier Analysis” in Program Options window.

For any subsequent clicks, instead, the saved “Start time” and “End time” are used.

Start and end time are not stored because these times are automatically computed when a Fourier chart is requested from the last part of the simulation: a period is estimated from the default frequency as specified in the Program Options window.

Automatic loading of files.

It may happen that you always (or very often) load the same files or files having the same name

In this case, in addition to the “save state” feature you have another option: specifying the files at command line.

If, for instance, in Microsoft windows you can create a link to PlotXY.exe in your folder containing “sample1.adf” and “rad2.mat” and writing in the program name after “PlotXY.exe” (without quotes) “rad2.mat sample1.adf” (without quotes). Your PlotXY will open and automatically load the two files.

You can list up to nine files as command-line parameters. They will all automatically load.

Customizing the program behaviour

We have already met in section named “Loading a file and doing first things” the “Program Options window.

There we saw the appearance of the “General” tab sheet. We also have other options to choose from in tab sheet named “Plot”, that is shown below here.

Their meaning is rather straightforward. Only the “Automatically assign units to known variables” might need some explanation and this is done in the following “Automatic Units of measure and prefix” section.

Note that when we hit the “Reset” button all program options stored on the PC, including program state (see “Saving Program State”)

And Fourier settings (see “Saving Fourier chart settings”) are reset, and the PC cleaned. At this point if PlotXY.exe is deleted, the PC is left totally cleaned of everything PlotXY has written on it.

Printing and exporting

Printing on paper or pdf

Plots can be printed on paper or pdf. The options at your disposal are those shown in the following diagram, that appears when you click on the “print” button of the plot window.

Exporting selected variables into a new data file

Very often files containing output from simulations or measure contain a lot of variables, while only a few of them are of interest for a given purpose.

PlotXY is able to create new files with such a subset of variables. Currently, however, saving only can be made from variables coming from the same input file. Thus, variables from different files or variables created using [The “function of variables” feature](#), cannot be saved.

To export the selected variables into a new data file click on the *Save vars* button of the in the *Data Selection* window.

Note that pl4 as output file type is only allowed when saving variables already belonging to a pl4 file. In this case the pl4 file created is of the so-called “pisa” format (or newpl4=2 format).

Exporting plot into system clipboard or SVG/PNG

Once you are satisfied with your plot you may want to export it somewhere.

Maybe you want to include it into a document file (e.g. Microsoft Word or OpenOffice writer): to do this you click on the *Copy* button on a Plot window, and then paste it into your favourite program. This way you get a pixmap copy (once called bitmap copy) of the plot.

As an alternative you can save you plots onto disk. In this case, you can obtain this result clicking, still in the plot window, on the *Save plot* button. You will get both a Portable Network Graphic (“PNG”) and a scalable Vector Graphic (“SVG”) plot copies on your hard disk. The PNG is a pixmap while SVG is a vector copy . The SVG

has the advantage that it can be manipulated using a SVG editing program (such as the freely available *Inkscape* from www.inkscape.org or the commercial Microsoft's Visio). In this way you will find that curves will remain curves (can be moved around as a single object, text items will remain text items, etc. Moreover zooming can be done without loss of visual quality.

SVG files can be drag&dropped in Word 2016 or PowerPoint 2016. In this case, Word and PowerPoint keep a local copy of the created SVG, which can be edited using your favourite SVG editing program (e.g. Inkscape). If you edit embedded SVG plots, the edited plots are embedded independently on the original drag&dropped file.

Note that another way to have a picture on file of your plots is to use the [Printing on paper or pdf](#) feature.

Additional information

Management of the plot windows.

PlotXY has a special architecture, which creates individual windows for individual plots, which are also separated from the main window, the DataSelection Window. When working on a cluttered desktop, it may happen that some of the plot windows finish below other windows (from other programs running).

To put on top of the desktop all the active plot windows, just select the DataSelection window, clicking on it.

On the other hand, to have in the DataSelection window the tab corresponding to a plot window to be displayed, select a plot window (or a Fourier window) clicking on it.

PlotXY is multiple-screen aware. If the system on which it operates has an extended screen, windows can be put on it, and saved. However, if when the program is restarted the extended screen is not available anymore, windows are moved into the primary screen so that they are visible and manageable.

Automatic determination of scale span

PlotXY contains an algorithm to determine automatically the span of the variables on the axes in such a way that the actual plot covers a large part of the plot rectangle (at least 80%) and the number on the axes are "round", i.e. they contain the least possible significant digits.

The following table, for instance, contains the axes extrema, which are computed with given minimum and maximum values of the displayed variable.

<i>Actual extrema</i>		<i>Rounded extrema</i>	
<i>Min</i>	<i>Max</i>	<i>Min</i>	<i>Max</i>
0	1.05	0	1.2
-1.05	1.05	-1.2	1.2
-1000	10	-1000	200

0.555	0.6	0.55	0.6
-0.007	100	0	100

The last row in the table is a special case: the software cannot find round extrema to contain the whole plot, but finds very nice ones that contains the (by far) large majority of it. In this case, he makes this choice, but signals this fact, using a grey-tick line for the plot rectangle, as shown aside here.

In this case, however, if the user clicks on the “Change Scale” button, he will have the opportunity of seeing the plot with the full ranges on the axes (figure below – left). However, in the case the purpose of showing “round” numbers on the axes is given up. (figure below right).

Note that not only the program chooses round numbers on the extrema, but also selects the number of tic-marks in such a way that the numbers on them are as round as possible and the number of them is reasonable, depending on the window's size. The user is prompted to experiment with this feature resizing the same plot and seeing how the intermediate tic-marks change in number. A tiny plot can have numerical labels just at the two extreme values.

Automatic Units of measure and prefixes

You may have noticed that in some plots units of measure (such as (V) or (kV)) have appeared.

This by default is automatically done by the program based on the following simple rules:

The “prefix”, substitutes the powers of ten, according to the standard notation, shown for completeness in the following table:

<i>prefix</i>	<i>meaning</i>	<i>prefix</i>	<i>meaning</i>
p	$\times 10^{-12}$	k	$\times 10^3$
n	$\times 10^{-9}$	M	$\times 10^6$
u	$\times 10^{-6}$	G	$\times 10^9$
m	$\times 10^{-3}$	T	$\times 10^{12}$

The units of measure are chosen as a function of the first character of the variable name, according to the following table:

<i>name begins with</i>	<i>assumed unit</i>	<i>symbol</i>	<i>name begins with</i>	<i>assumed unit</i>	<i>symbol</i>
'v'	volt	V			
'c'	ampere	A	'i'	ampere	A
'p'	power	W	'e'	energy	J
't'	time	s	'f'	frequency	Hz

Note that the correspondences on the last row are used for horizontal-axis variables only

You can disable this feature unchecking the “Automatically assign units to known variables” check box in the Program Options|Plot tab sheet (cf. section “Customizing the program behaviour”).

More on loading files

In section Loading a file and doing first things it was said that loading files can be done either using the Load... button, or dragging files on the Data Selection window. Here I supply some more details.

With both techniques, you can load individual files or groups of files. The program will adapt to different situations and behaves as expected. At the end of load operation more than one file is loaded, the program is in multi-file mode (it goes into this mode if it was in single-file mode).

However, when individual files are loaded starting from single-file mode, the program behaviour depends on whether the action is initiated from single-file or multi-file mode:

- when starting from multi-file mode the new loaded or dragged file is added to the already loaded ones
- when starting from single-file mode, the new loaded or dragged tile replace the currently displayed one.

It is recommended to try these differences: once you get accustomed, you can take advantage of them.

What else?

In this tutorial you have learnt all the major things you can do with PlotXY. You can learn the rest just by trying.

However, there are specific details on the structure of adf file or the rules that the program use to convert variable names into the supplied formats: for instance not all the names that are valid as ADF file or pl4 file names can be used as such in matlab files.

This more advanced documentation is provided document: “Input formats and naming conventions.pdf”
